

UNITED KINGDOM (UNK): England and Wales

Population: 53 million

Area: 244 046 km²

The designations and the presentation of material on this map of the Member States of the WHO European Region (as at 31 July 1997) do not imply the expression of any opinion whatsoever on the part of the World Health Organization concerning the legal status of any country, territory, city or area or of its authorities, or concerning the delimitation of its frontiers or boundaries. Dotted lines represent approximate border lines for which there may not yet be full agreement.

1. General information

1.1 Sources of data

There are three main national surveillance systems for gastrointestinal infection in England and Wales operated by the Public Health Laboratory Service Communicable Disease Surveillance Centre (PHLS CDSC). These are:

- The statutory notifications of food poisoning
- The national surveillance scheme for laboratory confirmed infections
- The national surveillance scheme for general outbreaks of infectious intestinal disease (IID)

In addition there is close liaison with the PHLS reference laboratories (Laboratory of Enteric Pathogens, Food Safety Microbiology Laboratory and the Enteric Virus Laboratory), all of which have national and international recognition for their reference facilities, and with external bodies such as the Veterinary Laboratories Agency, the Food Standards Agency, the Ministry of Agriculture, Fisheries and Food and the Department of Health.

The main characteristics of each of data source are outlined below.

1.2 Statutory notification of food poisoning

All doctors in clinical practice have a statutory duty to notify the proper officer of the local authority of all clinically diagnosed cases of diseases specified under the Public Health (Infectious Diseases) Regulations 1988. Food poisoning is one of the infections which is notifiable. In 1992 the Department of Health's Advisory Committee on the Microbiological Safety of Food (ACMSF) defined food poisoning as "any disease of an infectious or toxic nature caused by or thought to be caused by the consumption of food or water." This is a very sensitive definition of food poisoning which includes non-infective causes. Notification of food poisoning does not require that a laboratory diagnosis be obtained. Therefore, it is usually impossible to determine the number of cases of notified food poisoning attributable to specific organisms.

Notification data are collated nationally by CDSC on behalf of the Office for National Statistics (ONS). The collated data are published weekly in the Communicable Disease Report (CDR Weekly) which can be find at <http://www.phls.co.uk/publications/cdr.htm>.

For further reference on national and international data on foodborne diseases please visit the web page <http://www.who.it/docs/fdsaf/fddata.htm>.

1.3 National surveillance scheme for laboratory confirmed infections

Clinical microbiology laboratories in England and Wales voluntarily report data on microbiologically confirmed cases of infectious disease to the Public Health Laboratory Service Communicable Disease Surveillance Centre (PHLS CDSC). The data reported include:

- organism
- source laboratory (laboratory at which the specimen is initially examined)
- reference laboratory
- specimen date
- case identifier
- date of birth
- gender

The following events must occur cases to be included in the national surveillance database for laboratory confirmed infections:

1. an infected individual must consult a clinician (general practitioner or hospital doctor)
2. the doctor must arrange for a specimen to be taken and referred to a clinical microbiology laboratory
3. the laboratory must isolate or identify a pathogen
4. the laboratory must submit a report to the national surveillance centre

The national surveillance scheme for laboratory confirmed infections does not necessarily provide a direct measure of the numbers of cases of infection in the population caused by those pathogens under surveillance. A number of factors influence the degree of the disparity between the number of recorded laboratory reports for any given pathogen and the true number of cases of infection in the population. These include:

- severity of disease
- duration of symptoms

- selectivity of screening protocols employed by diagnostic laboratories
- sensitivity of available diagnostic techniques

The severity of the disease and the duration of symptoms associated with infection dictates both the proportion of cases that consult clinicians and the proportion of presenting cases from whom specimens are collected.

Laboratory screening protocols determine the investigations that are conducted on any given specimen so ascertainment of cases by laboratory report surveillance for any given pathogen is influenced by the laboratory screening protocols in operation.

There are variations in the sensitivity of the routine diagnostic techniques employed for different species and subtypes of pathogen. The sensitivity determines the proportion of cases that are identified by laboratory investigation. A range of microbiological techniques are which vary greatly in sensitivity and specificity. These include: light microscopy; isolation; immunoassays; novel techniques based on molecular biology.

Therefore it can be seen that the disparity between laboratory report surveillance data and infection in the community is lessened for pathogens that cause severe disease and for which laboratories screen widely using sensitive methods.

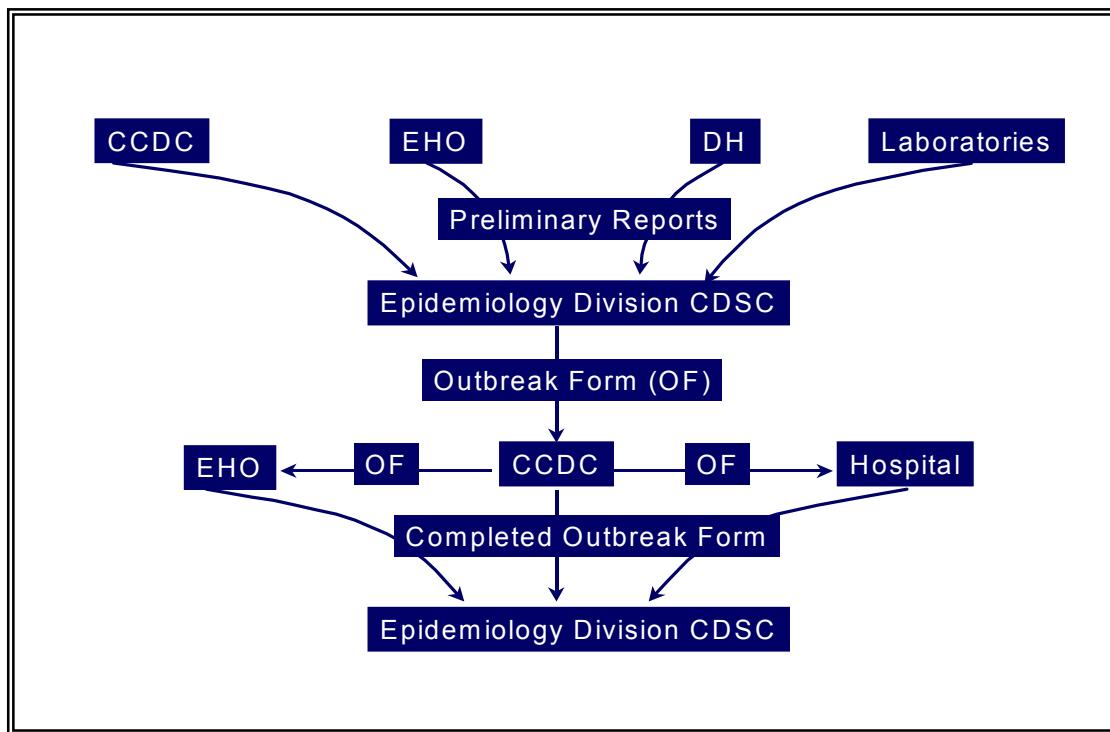

Despite these caveats, voluntary reporting of laboratory-confirmed cases is the most reliable means of determining trends in the major foodborne pathogens.

1.4 National surveillance schemes for general outbreaks of infectious intestinal disease (IID)

Since January 1992 enhanced surveillance of outbreaks of infectious intestinal disease has been conducted in England and Wales. General outbreaks are defined as outbreaks which affect people from more than one household. CDSC receives preliminary reports of general outbreaks of infectious intestinal disease (IID) from laboratories including the national reference laboratories, Consultants in Communicable Disease Control (CCDCs) in health authorities and local authority Environmental Health Officers (EHOs). Standardised questionnaires are then sent to the appropriate health authority in order to collect a minimum dataset on each outbreak. The investigating CCDC is asked to complete the questionnaire when the outbreak investigation is complete. The completed questionnaires are returned to the national surveillance centre and the data entered onto a database (Figure 1).

Figure GB-EW 1

OUTBREAK SURVEILLANCE

The following data are collected on the questionnaires:

- Health authority
- Date of outbreak
- Place of outbreak (hospital, restaurant, school, community etc.)
- Pathogen
- Mode of transmission (foodborne, person to person, mixed, other)
- For foodborne outbreaks
- Food
- Evidence (microbiological, epidemiological)
- Numbers of cases, admitted to hospital, deaths
- Faults associated with transmission of disease

Surveillance of general outbreaks of IID provides information on the specific risk factors associated with different pathogens and also trends in the importance of these factors. However the completeness of the surveillance data is mainly dependent on the sensitivity of detecting outbreaks at local level. The ease of identification of outbreaks is influenced by many of the same factors that affect laboratory report surveillance (see above).

2. Statutory notifications

2.1 Formally notified and otherwise ascertained cases of foodborne diseases

Notifications of food poisoning in England and Wales have risen steadily since the early 1980s. By 1998 more than 90 000 cases had been reported nationally. It is worth noting that following dissemination of the definition of food poisoning devised by the ACMSF a sharp increase in notifications occurred which is due to the inclusion of *campylobacter* infection in the food poisoning notifications.

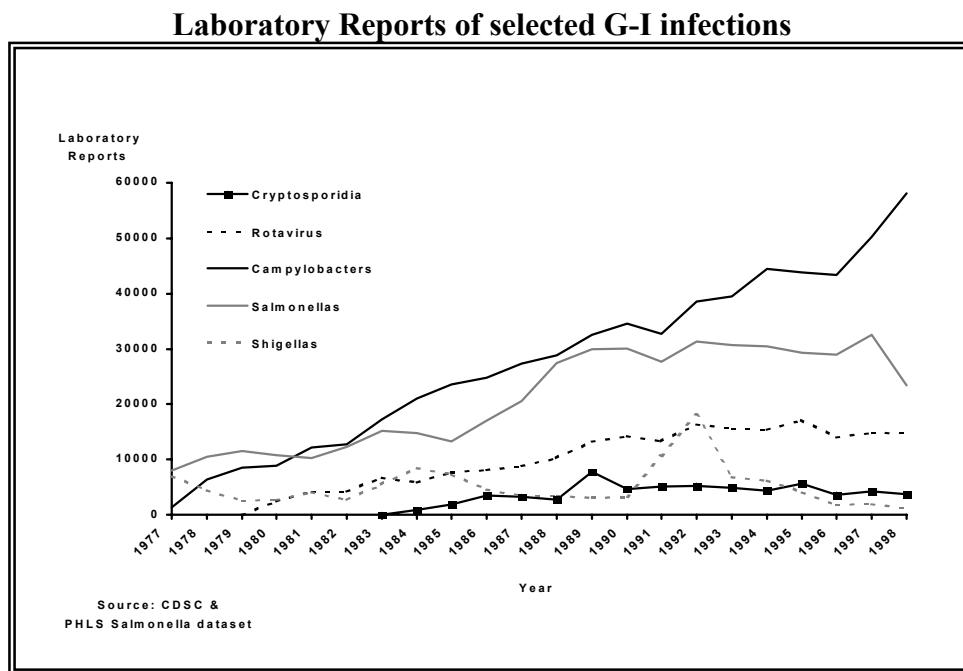

Figure GB-EW 2

2.2 National surveillance scheme for laboratory confirmed infections

The most noteworthy changes in reporting of laboratory confirmed infections in England and Wales were the continued rise in campylobacter infection and a sharp fall in reporting of salmonellosis (Figure 3).

Figure GB-EW 3

Campylobacter continues to be the most commonly identified bacterial cause of gastroenteritis in England and Wales. In 1997 the incidence exceeded 50 000 cases for the first time. It is rarely recognised as causing foodborne outbreaks.

Salmonellas are the second most commonly identified bacterial cause of gastroenteritis. The incidence of salmonellosis in England and Wales rose rapidly during the 1980s, a rise attributable to the emergence of *S. enteritidis* phage type 4. Poultry and eggs became contaminated with this strain. In 1998 the PHLS Laboratory of Enteric Pathogens reported just over 23 000 laboratory reports of salmonellosis to CDSC which was the lowest total for over a decade. It represented a 27% decrease on the previous year and laboratory confirmed cases of infection with virtually all major serotypes fell. It is too early to say whether or not this dramatic fall in incidence of salmonellosis in England and Wales is the start of a downward trend.

3. Epidemiologically investigated outbreaks

3.1 National surveillance schemes for general outbreaks of infectious intestinal disease (IID) England and Wales

Between 1993 and 1998 a total of 3 712 general outbreaks of IID were reported to CDSC of which 1 093 were foodborne (Table GB-EW 1).

* , Equal or unknown proportion of foodborne & person to person

† , In 1995 & 1996 enhanced surveillance of outbreaks of SRSV infection was undertaken, hence the number of salmonella outbreaks as a proportion of all outbreaks was lower than expected.

3.2 Causative agents

Causative agents: The predominant causative organism in foodborne outbreaks of IID was *Salmonella* sp. with *S. enteritidis* phage type 4 the most common (Table GB-EW 2).

Table GB-EW 2

Foodborne outbreaks – causative agents
England & Wales 1993-1998

3.5 Contributing factors

Food handling faults: Inadequate cooking, inappropriate storage of food and cross contamination were the most frequently reported food handling faults. Although infected food handlers were identified during the course of investigations it is not clear whether they are causes or victims of foodborne outbreaks. The possible exception to this is foodborne outbreaks of viral gastroenteritis where there are often reports that a food handler preparing the implicated food had symptoms e.g. vomiting into a sink where salad vegetables were being, or about to be, prepared.

Table GB-EW 7

Faults contributing to foodborne outbreaks England and Wales 1993-1998*

Contributory fault	Number of instances [†]	%
Infected food handler	119	10.2
Inadequate heat treatment	333	28.7
Cross contamination	286	24.6
Inappropriate storage	324	27.9
Other faults	100	8.6
Total	1162	100.0

Source: GSURV database, PHLS CDSC

* , For 367 foodborne outbreaks no contributory fault was reported.

† , More than one fault can be reported in each outbreak.
